

## The Human Eye

by Dennis Lange

Sight is precious to us and the human eye was designed with several protective features to ensure, if at all possible, our sight is preserved. Recessed into the eye socket, the eye is protected by the nose on one side, the cheekbone beneath and the ridge of the eyebrow above. Eyebrows offer protection from the sunlight. Eyelashes catch small things falling at difficult angles from above. The eyelid functions

reflexively like a windshield wiper to block objects coming head-on. It is self-lubricating and the periodic blinking of the eye spreads that moisture.

Sturmius, an 8th century believer, said, "Examination of the eye is a cure for atheism. Proof of God's existence stares back at us each day as we look in the mirror.

*Ps.139:14 I will give thanks to Thee, for I am fearfully and wonderfully made.*
