

Kangaroos

by Dennis Lange

Kangaroos are marsupials, animals whose young develop partially, are born, and then complete their development in pouches. At birth, the baby kangaroo is blind, three-fourths of an inch long, and must make a six-inch journey from the birth opening (the cloaca) to the pouch.

Would evolution's blind chance make sense in the survival of that blind baby kangaroo?

In the pouch, the tiny kangaroo attaches to a teat that pumps milk into it. When the joey finally leaves the pouch, it weighs about 20 pounds. A pair of pelvic girdle bones had to form to support the rim of the mother's pouch.

All this had to work perfectly the first time a blind baby kangaroo was born. The slow accidents of Darwin's gradualism make no sense.

Heb.3:4 For every house is built by someone, but the builder of all things is God.
